Journal	ASTRONOMY & ASTROPHYSICS
Volume	657

- Early results from HI studies of four MGCLS clusters (Sect. 9), including HI mass distributions in three clusters, and a new foreground HI group in the Abell 3365 field.

The results presented here represent only a small fraction of what can be achieved with the DR1 legacy dataset. Follow-up projects by the MGCLS team and the broader community are likely to make significant contributions to many areas of astrophysics.

Acknowledgements. The MeerKAT telescope is operated by the South African Radio Astronomy Observatory, which is a facility of the National Research Foundation, an agency of the Department of Science and Innovation. The authors acknowledge the contribution of those who designed and built the MeerKAT instrument. The authors thank the anonymous reviewer for their helpful comments which improved the manuscript. KK and ML acknowledge funding support from the South African Radio Astronomy Observatory (SARAO) and the National Research Foundation (NRF). WDC acknowledges support from the National Radio Astronomy Observatory, which is a facility of the National Science Foundation operated by Associated Universities, Inc. Partial support for LR comes from US National Science Foundation grant AST17-14205 to the University of Minnesota. Basic research in radio astronomy at the US Naval Research Laboratory for TEC is supported by 6.1 Base Funding. RPD, SR, and GL's research is funded by the South African Research Chairs Initiative of the DSI/NRF (grant ID: 77948). MR's research is supported by the SARAO HCD programme via the "New Scientific Frontiers with Precision Radio Interferometry" research group grant. VP acknowledges financial support from the South African Research Chairs Initiative of the Department of Science and Innovation and NRF. Opinions expressed and conclusions arrived at are those of the authors and are not necessarily to be attributed to the NRF. TV acknowledges the support from the Ministero degli Affari Esteri della Cooperazione Internazionale – Direzione Generale per la Promozione del Sistema Paese Progetto di Grande Rilevanza ZA18GR02. We thank E. Egami for providing access to ACREs data. Some results published here have made use of the CARACAL pipeline, partially supported by ERC Starting grant number 679629 'FORNAX', MAECI Grant Number ZA18GR02, DST-NRF Grant Number 113121 as part of the ISARP Joint Research Scheme, and BMBF project 05A17PC2 for D-MeerKAT. We acknowledge the use of computing facilities of the Inter-University Institute for Data Intensive Astronomy (IDIA) for part of this work. IDIA is a partnership of the Universities of Cape Town, of the Western Cape, and of Pretoria. This research made use of Astropy (<http://www.astropy.org>), a community-developed core Python package for Astronomy, and routines from the publicly available Astromatch package authored by A. Ruiz. It also made use of the SAOImageDS9 (Joye et al. 2003) software for image preparation, and the NASA/IPAC Extragalactic Database (NED) and NASA/IPAC Infrared Science Archive (IRSA), which are funded by the National Aeronautics and Space Administration and operated by the California Institute of Technology. *Chandra* X-ray Observatory data shown in this paper were accessed through the *Chandra* Data Archive (ObsIDs: 13380, 15173, 16283). *XMM-Newton* data shown in this paper were accessed through the *XMM-Newton* Science Archive (ObsID: 0720253401). The Digitized Sky Surveys were produced at the Space Telescope Science Institute under US Government grant NAG W-2166. The images of these surveys are based on photographic data obtained using the Oschin Schmidt Telescope on Palomar Mountain and the UK Schmidt Telescope. The plates were processed into the present compressed digital form with the permission of these institutions. DECam data were obtained through the Legacy Surveys imaging of the DESI footprint, which is supported by the Director, Office of Science, Office of High Energy Physics of the US Department of Energy under Contract No. DE-AC02-05CH1123, by the National Energy Research Scientific Computing Center, a DOE Office of Science User Facility under the same contract; and by the US National Science Foundation, Division of Astronomical Sciences under Contract No. AST-0950945 to NOAO. DECam data were also obtained from the Astro Data Lab at NSF's National Optical-Infrared Astronomy Research Laboratory. NOIRLab is operated by the Association of Universities for Research in Astronomy (AURA), Inc. under a cooperative agreement with the National Science Foundation. The Pan-STARRS1 Surveys (PS1) and the PS1 public science archive have been made possible through contributions by the Institute for Astronomy, the University of Hawaii, the Pan-STARRS Project Office, the Max-Planck Society and its participating institutes, the Max Planck Institute for Astronomy, Heidelberg and the Max Planck Institute for Extraterrestrial Physics, Garching, the Johns Hopkins University, Durham University, the University of Edinburgh, the Queen's University Belfast, the Harvard-Smithsonian Center for Astrophysics, the Las Cumbres Observatory Global Telescope Network Incorporated, the National Central University of Taiwan, the Space Telescope Science Institute, the National Aeronautics and Space Administration under Grant No. NNX08AR22G issued through the Planetary Science Division of the NASA

Science Mission Directorate, the National Science Foundation Grant No. AST-1238877, the University of Maryland, Eotvos Lorand University (ELTE), the Los Alamos National Laboratory, and the Gordon and Betty Moore Foundation. The Very Large Array Sky Survey (VLASS) is a project of the National Radio Astronomy Observatory, which is a facility of the US National Science Foundation operated under cooperative agreement by Associated Universities, Inc.

Appendix A: Extended source catalogues

Here we present the extended, multi-component source catalogues for the Abell 209 (Table A.1) and Abell S295 (Table A.2) cluster fields. (See the discussion in Sect. 5.3).

Table A.1. Extended sources in the Abell 209 MGCLS field.

(1) R.A. (deg)	(2) Dec. (deg)	(3) S_{int} (mJy)	(4) ΔS_{int} (mJy)	(5) I_{peak} (mJy beam $^{-1}$)	(6) LAS ($''$)	(7) Optical ID	(8) z

Notes. Cols: (1–2) Source J2000 R.A. and Dec. – the position is that of the optical host, or the flux-weighted centroid if no optical host is identified; (3–4) MeerKAT 1.28 GHz integrated flux density and its uncertainty; (5) MeerKAT 1.28 GHz peak brightness; (6) Largest angular size; (7) optical host identifier where known – number-only IDs are from DECaLS; (8) Optical host redshift.

Notes. Cols: (1–2) source J2000 R.A. and Dec. – the position is that of the optical host, or the flux-weighted centroid if no optical host is identified; (3–4) MeerKAT 1.28 GHz integrated flux density and its uncertainty; (5) MeerKAT 1.28 GHz peak brightness; (6) largest angular size; (7) optical host identifier where known – number-only IDs are from DECaLS; (8) optical host redshift.

Appendix B: Star-forming galaxy catalogue for Abell 209: SFR and radio–FIR

To carry out the environment-dependent studies discussed in Sect. 8.2, namely galaxy SFRs and the radio–FIR correlation in Abell 209, we needed to identify which of the MGCLS-detected sources belong to the cluster, remove AGN-dominated sources from that group, and calculate the SFR and the radio–FIR ratio. Here we discuss the details of these procedures and the creation of the Abell 209 star-forming galaxies catalogue being released as part of the DR1 products. This catalogue includes the SFRs and radio–FIR ratios for the cluster’s star-forming galaxies used in the scientific analyses presented in Sect. 8.2. An excerpt of this catalogue is shown in Table B.1.

B.1. Cluster galaxy membership

We assigned cluster membership using a combination of spectroscopic, z_s , and photometric, z_p , redshifts, with the latter determined using the zCluster photometric redshift code (Hilton et al. 2021) and photometry from DECaLS (Dey et al. 2019). The CLASH-VLT (Annunziatella et al. 2016) and ACRIS (Haines et al. 2015) spectroscopic datasets contain secure redshifts for 1256 and 345 galaxies in the Abell 209 field, respectively, with a combined total of 1425 unique galaxies. We define spectroscopic cluster member galaxies as those with peculiar radial velocities within $\pm 3\sigma_v$ of the cluster redshift,

where $\sigma_v = 1320 \text{ km s}^{-1}$ is the line of sight velocity dispersion (Annunziatella et al. 2016). Photometry-based cluster membership is defined as those galaxies with $|z_p - z_c| < 3\sigma_{\text{bw}}(1 + z_c)$, where z_c is the cluster redshift of 0.206 and $\sigma_{\text{bw}} = 0.03$ is the scatter in our photometric redshift residuals. This scatter is determined using a bi-weight scale estimate (Beers et al. 1990), and the residuals are calculated as $\Delta z / (1 + z_s)$, where $\Delta z = z_s - z_p$.

We obtained a final catalogue of 523 MGCLS-detected cluster members within the primary-beam-corrected field of view, with 98 members within R_{200} . We determine the amount of contamination in the photometric redshift sample using the 91 member galaxies with both spectroscopic and photometric redshifts²⁵. We find that 16% of the members selected using photometric redshifts have spectroscopic redshifts outside the photometric redshift cut range, while 23% of the spectroscopically identified cluster galaxies are missed by the photometric redshift selection.

B.2. AGN contamination

To separate star-forming galaxies from AGN-dominated galaxies, we used the ‘R90’ WISE infrared-selection criteria by Assef et al. (2018) (see also Stern et al. 2012; Assef et al. 2013). These utilise only the WISE W1–W2 colour to identify AGN without a threshold that depends on the W2 band magnitude

²⁵ For galaxies that have both a spectroscopic and photometric redshift, inclusion as a cluster member is defined by the spectroscopic redshift.

(see Eq. (4) of [Assef et al. 2018](#), which identifies AGN with 90% reliability). With this selection method, we classify 64 radio-detected cluster galaxies as AGN and remove them from the cluster member sample. This leaves a total of 459 MGCLS-detected star-forming cluster members within the primary-beam-corrected field of view (80 within R_{200}). Table B.1 presents an excerpt of the catalogue of star-forming cluster galaxies in Abell 209.

B.3. Radio-derived star-formation rates

To estimate the SFR from the radio luminosities we used the [Bell \(2003\)](#) relation (see also [Karim et al. 2011](#)) scaled to a [Chabrier \(2003\)](#) IMF:

$$\text{SFR (M}_{\odot} \text{ yr}^{-1}) = \begin{cases} 3.18 \times 10^{-22} L, & L > L_c \\ \frac{3.18 \times 10^{-22} L}{0.1 + 0.9(L/L_c)^{0.3}}, & L \leq L_c. \end{cases} \quad (\text{B.1})$$

Here, $L = L_{1.4 \text{ GHz}}$ is the radio luminosity in W Hz^{-1} derived from the MGCLS 1.28 GHz total flux density, using a power law scaling and assuming a non-thermal spectral index of -0.8 ([Condon 1992](#)). $L_c = 6.4 \times 10^{21} \text{ W Hz}^{-1}$ is taken to be the typical radio luminosity of an L_* galaxy. [Bell \(2003\)](#) argued that galax-

ies with low luminosities could have their non-thermal emission significantly suppressed and therefore need to be separated from the population with higher pg luminosities. However, as only a small percentage (39/459) of the final sample have luminosities lower than L_c , we do notpg separate according to luminosity. We measure SFRs ranging between 1.2 and $432 \text{ M}_{\odot} \text{ yr}^{-1}$, within the range of knownpg values. Under the assumption that the radio emission is due to star formation, the median 5σ sensitivity limit corresponds topg $\text{SFR}_{5\sigma} > 2 \text{ M}_{\odot} \text{ yr}^{-1}$, with 429/459 star-forming members with SFRs above this limit.

B.4. FIR cross-matching for radio–FIR correlation

In order to study the radio–FIR correlation in Abell 209, we first need to determine FIR flux densities for the cluster star-formingpg galaxies. We cross-match the catalogue of 459 star-forming members with the *Herschel* $100 \mu\text{m}$ catalogue²⁶. This yielded 49 star-forming cluster galaxies with both 1.28 GHzpg and $100 \mu\text{m}$ flux densities. We use the log of the ratio of these two quantities to investigate evolution in the radio–FIR relation.pg The *Herschel* $100 \mu\text{m}$ flux densities for the 49 galaxies and associated radio–FIR ratio are provided in the Abell 209pg star-forming galaxies catalogue shown in Table B.1.

Table B.1. Excerpt of the SFR and infrared catalogue of star-forming cluster galaxies in Abell 209, used in the SFR and radio–FIR studies in this paper (Sects. 8.2.1 and 8.2.2, respectively). The full catalogue is available online.

Notes. The first column is an assigned source ID for the radio source. Column descriptions for columns (2)–(28) (not shown here) are the same as in the optical cross-match catalogue, described in Table 3. The additional columns are: (29) spectroscopic redshift; (30) catalogue from which the redshift was obtained; (31–32) SFR and uncertainty; (33) radius from the centre in units of R_{200} ; (34–35) $100 \mu\text{m}$ flux density and uncertainty; (36–37) log of the ratio between the radio and FIR flux densities, and associated uncertainty.

Appendix C: Automated searches for interesting objects

The definition of an ‘unusual’ radio object is subjective and dependent on the science case of interest. In the search for radio galaxies of interest, several of which are presented in Sect. 7, the MGCLS dataset was small enough for human inspection. However, it took a significant amount of time, with all images inspected by several people and the final set of radio galaxies of interest determined after cross-checking the various choices. For future surveys, exhaustive human searches for unusual objects may be impossible. We therefore used the MGCLS to examine the efficacy of machine learning techniques to find atypical, interesting objects.

ASTRONOMALY (Lochner & Bassett 2021) is a machine learning framework designed to automatically detect anomalous (rare or unusual) objects in very large datasets. We ran ASTRONOMALY on $128\text{ px} \times 128\text{ px}$ ($160'' \times 160''$) cutouts around components from the PYBDSF source finding (see Sect. 5), using the same framework as Lochner & Bassett (2021). To compare our results with those from human

inspection, we restricted our search to the cluster fields where we had visually identified at least one extended radio galaxy with complex and/or unusual morphology (approximately 40% of the full sample). For those fields, we centred cutouts on components that were classified as having two or more Gaussian components by PYBDSF, which resulted in 21,449 cutouts.

We used ASTRONOMALY’s anomaly score to order the data from most to least anomalous, comparing this list with a selected set of 43 sources that were previously identified as ‘interesting’ by one or more team members. Cutouts of the top 10 scoring objects are presented in Fig. C.1. Of the 43 interesting objects, ASTRONOMALY detected 22 in the top 1% (210 objects) of the rankings. Forty out of 43 sources are found in the first 10% of the list, while the remaining three could not be distinguished from ‘normal’ sources. We note that the vast majority of the 210 most highly ranked sources²⁷ are actually visually quite similar to the selected 43. We conclude that ASTRONOMALY can be a useful tool for rapid searches of morphologically interesting objects in large catalogues of radio sources, from which more targeted manual searches can be made efficiently.

Fig. C.1. Ten top-ranked cutouts based on their ASTRONOMALY score. The cutouts are each $160''$ per side, and their respective cluster fields (and cutout centres, in degrees of R.A., Dec.) are as follows: A: J0216.3–4816 (34.190, -47.836); B: J1423.7–5412 (214.984, -54.102); C: Abell 22 (5.055, -24.925); D: Abell 194 (21.502, -1.345); E: Abell S295 (41.422, -52.962); F: J0607.0–4928 (92.267, -48.900); G: Pandora (4.279, -29.934); H: J0216.3–4816 (33.252, -47.690); I: Abell 194 (21.522, -1.446); and J: J0738.1–7506 (114.851, -75.618). We note that sources D (and its extension to the south, identified as a separate source, I) and J are among the individual sources identified manually (independent of ASTRONOMALY) and selected for discussion in Sect. 7.
